Emerging equity markets in a globalizing world

Given the dramatic globalization over the past twenty years, does it make sense to segregate global equities into “developed” and “emerging” market buckets? Geert Bekaert (Columbia University) and Campbell R. Harvey (Duke University) argue in this paper that the answer is still yes. While correlations between developed and emerging markets have increased, the process of integration of these markets into world markets is incomplete. Interestingly, this incomplete integration along with the relatively small equity market capitalization creates potentially attractive investment opportunities. This has important policy implications for institutional and pension fund management.

Netspar stimulates debate and fundamental research in the field of pensions, aging and retirement. The aging of the population is front-page news, as many baby boomers are now moving into retirement. More generally, people live longer and in better health while at the same time families choose to have fewer children. Although the aging of the population often gets negative attention, with bleak pictures painted of the doubling of the ratio of the number of people aged 65 and older to the number of the working population during the next decades, it must, at the same time, be a boon to society that so many people are living longer and healthier lives. Can the falling number of working young afford to pay the pensions for a growing number of pensioners? Do people have to work a longer working week and postpone retirement? Or should the pensions be cut or the premiums paid by the working population be raised to afford social security for a growing group of pensioners? Should people be encouraged to take more responsibility for their own pension? What is the changing role of employers associations and trade unions in the organization of pensions? Can and are people prepared to undertake investment for their own pension, or are they happy to leave this to the pension funds? Who takes responsibility for the pension funds? How can a transparent and level playing field for pension funds and insurance companies be ensured? How should an acceptable trade-off be struck between social goals such as solidarity between young and old, or rich and poor, and individual freedom? But most important of all: how can the
benefits of living longer and healthier be harnessed for a happier and more prosperous society?

The Netspar Panel Papers aim to meet the demand for understanding the ever-expanding academic literature on the consequences of aging populations. They also aim to help give a better scientific underpinning of policy advice. They attempt to provide a survey of the latest and most relevant research, try to explain this in a non-technical manner and outline the implications for policy questions faced by Netspar’s partners. Let there be no mistake. In many ways, formulating such a position paper is a tougher task than writing an academic paper or an op-ed piece. The authors have benefitted from the comments of the Editorial Board on various drafts and also from the discussions during the presentation of their paper at a Netspar Panel Meeting.

I hope the result helps reaching Netspar’s aim to stimulate social innovation in addressing the challenges and opportunities raised by aging in an efficient and equitable manner and in an international setting.

EMERGING EQUITY MARKETS IN A GLOBALIZING WORLD

Abstract
Given the dramatic globalization over the past twenty years, does it make sense to segregate global equities into “developed” and “emerging” market buckets? We argue that the answer is still yes. While correlations between developed and emerging markets have increased, the process of integration of these markets into world markets is incomplete. To some degree, this accounts for the disparity between emerging equity market capitalization in investable world equity market benchmarks versus emerging market economies in the world economy. Currently, emerging markets account for more than 30% of world GDP. However, they only account for 12.6% of world equity capitalization. Interestingly, this incomplete integration along with the relatively small equity market capitalization creates potentially attractive investment opportunities. Our research has important policy implications for institutional and pension fund management.
1. Introduction

Twenty years ago, the World Bank organized a conference on “Portfolio Flows to Emerging Markets”. At the time, the World Bank had recently compiled the first-ever database of emerging market equity returns. Foreign portfolio (as opposed to direct) investment was relatively new. The theme of the conference was to better understand the risks that portfolio investors faced in their emerging market investments and to study why emerging markets were different from developed markets.

Today, the issue is not whether to invest in emerging markets—but how much to invest in emerging markets. However, even after twenty years of research, there are still some unanswered questions. Our paper addresses these questions:

– Has the risk profile of emerging markets changed?
– Are emerging markets more integrated into world markets today?
– How much of a diversified global equity portfolio should be allocated to emerging markets?

Indeed, our paper addresses an even broader question – should we even bother to distinguish between emerging and developed markets? As early as 2002, Saunders and Walter (2002) claimed that the continued capital market liberalizations across developing countries obviated the need to separate emerging and developed equity market classes. Despite further globalization since then, our conclusion is different: Emerging markets should still be treated as a separate asset class.

Our research has important policy implications for institutional and pension fund management. Emerging markets are not fully integrated within global capital markets yet, and deserve to be a separate asset class. New sub-segments (currencies, bonds)
should be considered as well. The relative market capitalization of emerging markets is much lower than their relative economic weight, so that a market capitalization-based benchmark can be viewed as a lower bound on the asset allocation to emerging markets. Over the last 15 years, emerging equity markets transformed from an asset class exhibiting very low correlations with the rest of the world to one with a relatively high world market beta: risky but high expected returns.

Our paper is organized as follows. Section two examines the role of emerging markets in the world economy and compares the share of emerging markets' GDP relative to world GDP to their share of world equity markets. The unique risk characteristics of emerging markets, as well as their evolution through time, are detailed in section three. Section four discusses the degree of integration of emerging markets within global capital markets, and how it has evolved through time. The case for portfolio allocation to emerging markets is examined in section five. Section six focuses on non-equity asset classes that are available in emerging markets. Some concluding remarks are offered in the final section.
2. The increasing role of emerging markets in the world economy

In the late 1980s, the US and Japan accounted for 46.3% of world GDP, whereas China accounted for less than 1.5% of world GDP. By 2012, China's share grew to 11.5%, whereas the share of the US and Japan fell to 30.2%.

As Exhibit 1 shows, China, Brazil, Russia and India all feature in the top ten in terms of contribution to world GDP. It is reasonable to expect that the GDP share of today's emerging markets will soon exceed the GDP share of developed markets. In fact, projections of the World Bank, reproduced in Exhibit 2, suggest as much.

Notice that emerging market GDP represented about 10% of world GDP in 1987. Yet at that time, the equity market capitalization was very small – less than 1% of the world market capitalization according to Morgan Stanley Capital International (MSCI) data, as shown in Exhibit 3. The exhibit also shows the rapid growth in market capitalization over the last decade.

Exhibit 3. Equity Market Capitalization of Emerging Markets

Source: MSCI
By the beginning of 2012, the market capitalization weight for emerging markets according to MSCI is 12.6%. The FTSE benchmark market capitalization weight for emerging markets was 11.5%. The difference between FTSE and MSCI has to do with the countries that are classified as “emerging”. The most significant difference is South Korea, which accounts for 2.2% of global equity market capitalization. In the FTSE global index, South Korea is a “developed” market, whereas MSCI puts South Korea in the “emerging” market group. There are other smaller differences. The different approaches to including South Korea speak to one of our fundamental questions: should we bother to distinguish between emerging and developed markets?

While both the GDP and market capitalization share of emerging markets have grown, they have failed to converge. By 2012, emerging markets accounted for more than 30% of world GDP, yet only 12.6% of equity market capitalization. The US, in contrast, currently accounts for 25% of world GDP, and about 45% of world equity market capitalization (according to the MSCI ACWI, which has a broader coverage of emerging markets than the MSCI World Index).

There are economic reasons that, in part, explain the gap between the share of world GDP and the share of world equity. In many developing countries, banks provide the main source of financing for firms. Indeed, there is significant variation in financing patterns across developed countries as well (see e.g. Beck, Demirguc-Kunt and Maksimovic, 2008), and the relative size of equity markets varies wildly even among developed countries. For example, Germany and Italy have relatively small equity markets, whereas the Anglo Saxon countries have relatively large stock markets. What is interesting is the apparent lack of convergence even as equity financing is a viable financing channel

Exhibit 4. Emerging Markets’ GDP and Equity Market Shares

![Graph showing the weight of emerging markets compared to GDP over time.]

Source: World Bank, IMF, MSCI

In many large emerging markets. Indeed, Exhibit 4 suggests that the gap between GDP and the size of the equity market has widened in recent years.

Exhibit 5 drills down to the country level. In the MSCI All Country World Index (MSCI ACWI), of the ten countries most underweighted relative to their GDP weights, six are emerging markets – with China the most underweighted.

There is one additional, important consideration. First, providers such as MSCI and FTSE do not count all of the market capitalization. They focus on the “free float”. Some of the capitalization may not be easily available for transactions because, for example, it is held by a government. Emerging markets have much lower proportions of free float than developed markets have. Exhibit 6 shows that in the MSCI emerging markets, the free float to total market capitalization is only 55% on average. In contrast, in the US, the ratio is 94%. Note that MSCI only changed
the ACWI in 2002 to reflect the difference between total market capitalization and free float.

However, the free float does not account for all of the underweighting. Exhibit 7 revisits Exhibit 4 – but adding a total capitalization version of the MSCI ACWI.

While the emerging markets share of free float is 12.6%, the share of total market capitalization is 20.0%. Nevertheless, this is far short of the near 35% share of GDP they represent.

3. Risk characteristics of emerging markets

The combination of home bias and the prevalence of market capitalization benchmarks in investing leads to emerging markets accounting for much less than their economic weight in investment portfolios in the developed world. To assess the attractiveness of emerging market equity investments, we now consider the risk and expected return characteristics of emerging market returns.

Exhibit 8: Comparing the Total Return Performance of Developed and Emerging Markets (January 1988 to August 2013)

Note: The geometric average is used for average annualized excess returns above. Returns are in excess of a US Treasury bill. Source: MSCI and the St. Louis Federal Reserve.
Examining the history of the MSCI indices in Exhibit 8, emerging markets have historically outperformed developed markets. The geometric average excess return (over and above a US Treasury bill) for emerging markets over the sample was 8.0%, compared to only 3.7% for developed markets (MSCI World). Because the emerging market index has much higher volatility than the world indices have, we use geometric averages in these calculations. The standard deviation of emerging market returns is 23.8%, compared to only 15.3% for the diversified world index. Even though the volatility is much higher, the Sharpe ratios for emerging markets are still higher. The difference is even more dramatic in the most recent ten years, when the 2008–2009 financial crisis substantially undermined the performance of developed markets. Despite being hit severely by the crisis as well, some large emerging markets, such as Brazil, Russia and South–Africa, nevertheless more than tripled over the last decade. The five–year trailing excess geometric returns in Exhibit 9 show a very large run–up in emerging markets during most of the past decade, and very few negative five–year returns are observed for emerging markets over the last ten years.

Note that higher volatility of the emerging market portfolio is not at all surprising and, in part, reflects the large weight of the relatively low–volatility US market in the world market index and the diversification effect of investing in all of the world’s equity markets. Individual emerging markets have very high volatility, ranging from 27% for South Africa to 54% for Russia (using data from 1988 to September 2013). The volatility of the emerging markets composite index is much lower than the individual volatilities of separate emerging market countries, and it is about as high as the volatility of some larger developed countries such as Japan or Germany. The rolling five–year standard deviations in
Exhibit 9: Annualized USD five-year excess returns

Note: Geometric returns are used. Returns measured in excess of US Treasury bill rate. Source: MSCI and St. Louis Federal Reserve.

Exhibit 10 show that the volatility of the emerging market index has fluctuated in the 17% to 30% band – but is lately closer to the upper end of that range.

Risk should not simply be measured by standard deviation, however. It is well known that emerging market returns are not normally distributed; see Bekaert, Erb, Harvey and Viskanta (1998). It is important to consider downside risk as well. Exhibit 11 shows that the emerging market index does not show substantially more non-normalities than the MSCI World index, exhibiting similar skewness at -1.6 and only slightly more excess kurtosis at 1.6. Note that individual emerging markets actually mostly exhibit positive skewness, but the growth experiences appear country-specific, whereas some of the downside moves are common
across countries, causing negative skewness at the index level. Taking together all of the risk characteristics, emerging markets definitely have more downside risk. The 99% VaR for emerging market returns is −24.6%, compared to only −14.7% for developed markets. Of course, this is largely caused simply by the higher variance of emerging market returns.

From an investment perspective, the absolute risk of emerging markets is largely irrelevant. Investors in developed markets will invest only a portion of their portfolio in emerging markets, and therefore the correlation between developed markets and emerging markets will be an important driver of the ultimate risk borne. When emerging markets were first touted as interesting investments for global investors in the early 90s, their diversification benefits were emphasized. The emerging market

Note: Simple average monthly total returns are shown above. Average monthly return is not annualized. Standard deviation is that of monthly returns, also not annualized. Both skewness and kurtosis are defined in the standard way; kurtosis is excess kurtosis here. Value-at-Risk is the realized monthly percentage loss at the relevant threshold. Conditional Value-at-Risk is the average loss once the threshold has been exceeded. Average negative and positive returns are simple averages conditional on the returns being negative or positive respectively. Source: MSCI

index had a correlation with the world index of about 0.40, leading to considerable diversification benefits. However, this correlation has increased over time (also, see Fernandes, 2005). As Exhibit 12 shows, more recently the correlation stands at 0.90. It is easy to explain some of the initial increases in correlations. At the end of the 1980s and the beginning of the 1990s, many emerging markets embarked on a liberalization process; these stock market liberalizations drove up the correlations with the rest of the world (see Bekaert and Harvey, 2000; Henry, 2000). Since then, however, the gradual increase in correlations has continued, making diversification benefits a poor rationale for investing in emerging markets.
The correlation between two markets can be expressed as the product of the beta times the ratio of standard deviations. Using this decomposition, the increasing correlations are partly the result of higher betas with respect to the world market, as shown in Exhibit 13. The other component in the heightened correlation is a 10% increase in the world versus emerging market volatility ratio (see Exhibit 9). Betas now seem to fluctuate in a 1.2–1.6 band, making emerging markets a risky, high–expected–return asset class. Importantly, the higher betas are not sufficient to explain the higher returns earned by emerging markets over the last 20 years. As Exhibit 8 shows, the historical “alpha,” the additional return over and above the return commensurate with exposure to the world market, was almost 5% per year since 1988.
The high average correlations hide some interesting dynamics. Exhibit 14 separates positive and negative performance. Emerging markets perform similarly to developed markets when developed market returns are negative. However, emerging markets outperform developed markets when developed market returns are positive. Again, this analysis is based on averages, and this measure as well as correlation could be affected by influential observations. In addition, the historical behaviour is only suggestive of future return patterns. Nevertheless, it is somewhat reassuring that the above pattern was realized in the period surrounding the recent financial crisis. In other words, the downside of emerging markets is less severe than the beta computations would suggest. If the beta would truly be higher than 1, emerging markets would under-perform when developed
markets do poorly, but Exhibit 14 suggests they perform about as well. This result is consistent with recent results on non-linear dependence in emerging market returns by Christoffersen, Errunza, Jacobs and Langlois (2013) and with recent work on contagion during the global crisis (see Bekaert, Ehrmann, Fratzscher and Mehl, 2013).

4. Market integration

But are emerging markets still “different”; do they constitute a separate asset class? The way an academic would pose that question is to ask whether emerging markets are effectively “integrated” in global capital markets. In integrated world markets, a project of the same risk (say, a particular type of industry), should command the same expected return – no matter where the project is located. If a market is not integrated, we refer to the market as segmented. In reality, there is a continuum of possibilities between segmentation on one extreme and integration on the other.

It is well known that many emerging markets are not fully integrated into world markets (see Bekaert and Harvey (1995, 2000) and Bekaert et al. (2011)). Segmentation is first and foremost caused by regulations that make it difficult for foreign investors to buy equity in particular countries.

The stock market and more general financial liberalization process that took place at the end of the 80s and throughout the 90s relaxed a lot of these regulations, creating the emerging market asset class in the process. The globalization process may serve to integrate emerging markets with global capital markets, but how do we measure it? Exhibit 15 focuses on two aspects of (de jure) globalization. The first is economic openness, as measured by the Trade Liberalization Dummy taken from Wacziarg and Welch (2008). Wacziarg and Welch (2008) call a country open to trade when it satisfies a number of criteria regarding tariff and non-tariff barriers. It is a zero-one dummy. The second aspect is financial openness, for which we show two indicators: the Capital Account Openness Index from Quinn and Toyoda (2008), and the Equity Market Openness indicator from Bekaert, Harvey and Ng
(2005). The capital account index scores the degree of capital account openness between 0 and 1, based on IMF data. The equity markets measure takes the ratio of "investable" to total market capitalization.

We take these 0/1 measures for 50 countries, average them and graph them over time. The graph shows that there is a very clear trend upwards towards more openness. For trade, the world is "open", but there is some way to go towards full openness for capital account openness and equity market openness. In fact, in the recent global crisis, we most definitely witnessed a globalization reversal, but our measures are too coarse to pick this up.

For global asset managers, globalization has had 'grave' consequences. As discussed before, globalization has led to increased country correlations, has changed systematic risk measures, and may lead to substantial changes in global asset
allocation. However, the integration process is far from complete. The third largest market in the world (China), for example, is largely closed to foreign investment. More importantly, a relaxation of restrictions on foreign investors does not necessarily lead to integration, as other factors may effectively segment the market from global capital markets. A good example is extreme political risk, which may keep out important institutional investors who are restricted to invest in investment-grade countries. Another example is corporate governance.

Exhibit 16 compares and contrasts a set of country governance and political risk indicators. Today, there is still a sharp contrast
between emerging and developed markets with emerging markets showing mostly medium to low scores on these indicators of corporate governance, political stability and corruption. Even within emerging markets, there is considerable variance. For example, both China and Russia score the highest possible rating on the Enforcement of Contracts measure. However, they score the lowest rating on Property Rights. While this may reflect noise in the ratings, both countries are known not only for reasonably well-functioning legal proceedings, but also for governments that may arbitrarily seize property of their citizens and/or foreigners. These factors may serve to segment markets, but they can also create expected return opportunities for global investors. For example, Erb et al. (1996) argue that political risk is priced, and therefore that emerging markets exhibiting severe political risk may offer attractive expected returns — as long as the political risk factor eventually reverts to normal levels. More generally, special risk factors that cause emerging markets to be partially segmented from global markets may cause emerging markets to trade more cheaply than developed markets. This “emerging market discount” is apparent in Exhibit 17, where we graph the MSCI price–earnings ratios for the world market and the emerging market index. These ratios are calculated by dividing total market capitalization by total earnings. Through the mid-90s, emerging markets traded at much lower multiples than developed markets, but since then there has been some convergence of price multiples. Note that these index averages do reflect large cross-country dispersion in valuation ratios. Also, the PE ratio may reflect to a considerable extent the unique industry structure of a country.

In a recent paper, Bekaert, Harvey, Lundblad and Siegel (BHLS, 2011) develop a measure of the degree of effective market
segmentation (SEG) using valuation measures carefully controlling for cross-country variation in industry composition. With their SEG measure in hand, they ask questions such as: Has the degree of effective segmentation decreased over time? What was the role of the *de jure* globalization? What other factors drive valuation differentials across countries and time? The SEG measure views each country as a basket of industries, weighted by their market capitalization. The proposed segmentation measure takes absolute differentials between the industry earnings yield\(^1\) (the inverse of the PE ratio) and the earnings yield of that industry at the world level – doing this for 38 different industries. The market capitalization weighted sum of these absolute differentials is the country segmentation measure.

---

1 Earnings yields are preferred over the price-to-earnings ratios because if earnings are small or zero, the PE ratios are extremely large – or infinite.
If countries are integrated, the SEG measure should be very small and relatively constant through time. This is because the discount rate and the growth rate of (expected) dividends should converge for the same industries in different countries if these countries are truly integrated. This strong concept of market integration assumes that industries have identical systematic risk across the globe and that growth opportunities are industry-specific but global in nature. The latter assumption is plausible if growth opportunities are primarily driven by technological factors and capital markets are totally free. The valuation differential measure ignores financial risk, but country-specific regulations may induce differences in leverage ratios, which affect valuations. The use of absolute values implies that a low number of firms within an industry group may cause “noise” and upwardly bias the measure. Lastly, earnings volatility may be priced, and cause price differentials even across integrated firms. Because the valuation differential can be measured at each point in time, controlling for these factors in a regression analysis is possible.

Exhibit 18 shows the earnings yield differentials for developed and emerging markets. The earnings yield differential was around 4.5% in the 1970s for developed markets, but is now around 2%. For emerging markets, the differential went from around 10% to about 4%. Hence, there is indeed a downward trend, with earnings yield differentials converging worldwide.

But how high or low is 2%? Because of the use of absolute values, a value of 0 is not the right benchmark. What level of segmentation would be observed in an integrated world? To get a grip on this, BHLS perform a simulation experiment. They use US data to construct a segmentation measure for a non-segmented equity market. Specifically, they construct 100 data sets from random draws of US firms, and use the overall US market as
the “world” market. That is, the US serves as an “integrated planet”, and random samples of US stocks are used to create 50 pseudo-countries, which replicate the cross-sectional and temporal variation in the number of firms in the actual sample of countries. The SEG index for the “integrated” world then produces a 5% – 95% a confidence bound for the measure. Using these bounds, Exhibit 18 also shows that developed markets have effectively converged since the mid-1990s. Emerging markets have also moved toward convergence, but are still slightly above the 95% confidence band. As such, emerging markets are still not fully integrated within global capital markets and are rightfully still a separate asset class. Eun and Lee (2010), studying risk-return distance between developed and emerging markets, also show convergence, but conclude that emerging markets are still distinct, as do Carrieri, Chaieb and Errunza (2013), based on a study of implicit investment barriers in emerging markets.

Exhibit 18. Market Segmentation
BHLS also assess the determinants of valuation convergence, by running panel regressions of the SEG measure onto a large set of factors as potential determinants of valuation differentials. They find that a relatively parsimonious set of variables explains the cross-sectional and time series variation quite well, including de jure openness, investment profile (a measure of political risk from the International Country Risk Guide), and the VIX and corporate bond spread. The latter two variables can be considered as measures of risk aversion and/or risk premiums. Thus, in a crisis, you would expect valuation differentials to diverge and segmentation to increase. This did happen in the recent global financial crisis.

The relative higher degree of “segmentation” of emerging markets is also reflected in the dominance of “country factors” (as opposed to “industry factors”) as drivers of variation in

Exhibits 19 and 20 detail the amount of the cross-sectional variance in developed and emerging market returns that is accounted for by industry factors and country factors. For developed markets, both industry and country factors contribute about equally to the cross-sectional variance. For emerging markets, it is a much different story: country factors are twice as important as industry factors, confirming the results of Phylaktis and Xia (2006), whose data set ended in 2002.

Estimates are based on the Barra Global Equity Model, which includes 55 country factors, 34 industry factors, 8 style factors and 55 currency factors. The sum of country and industry contributions is not 100% because we omit from the graph the contribution of the style factors.
5. The case for emerging markets revisited

At first blush, some of the recent developments have made emerging markets less attractive investments. Globalization has increased country return correlations with developed markets, and valuations seem to have somewhat converged. In addition, an investment in any individual country is very volatile. However, the high individual country volatility is exactly what an active asset manager is looking for. The high volatility and country factors create opportunities for out-performance. For example, if you were to record the best- and worst-performing equity markets since 1990; you would find that in more than 90% of the cases, it’s an emerging market.

One way to formalize this potential is to examine the cross-sectional volatility in emerging versus developed markets. We plot this cross-sectional volatility over time in Exhibit 21. While the cross-sectional volatility in emerging markets was higher than in developed markets up to 2000, the differences have decreased over the last ten years. One potential reason is the continuing integration of emerging markets within global capital markets and the recent global crises that have affected many countries simultaneously.

So, emerging markets remain an attractive asset class for very simple reasons. First, country factors still dominate cross-country valuations. Investment barriers and other country factors are priced, but “risk appetite” factors are important as well. The country factors are nowhere larger than in emerging markets, leading to high country-specific volatility. Second, a diversified basket of emerging markets is not risky. It has about the same volatility as the larger developed markets. Third, the globalization process has led to valuation convergence, but the process has
not been smooth. This, in itself, may provide opportunities for excess returns from global tactical asset allocation programs. Fourth, emerging markets account for less than 15% of market capitalization but more than 30% of GDP. This is no guarantee for outperformance, as most of the catch-up should come through share issuances. However, as the last decade has shown, some emerging markets, such as Brazil, really took off and had very high returns during the decade at a time where many developed markets had dismal returns. It is hard to predict which markets will be next. But you are not in them at your peril. To the extent that valuation convergence has not completely eliminated the emerging market discount, some of the gap between in-market

Exhibit 21. Cross-Sectional Volatility: Emerging vs. Developed Markets

Note: Cross-sectional standard deviation of country returns is calculated every month (separately) for emerging and developed markets. The above exhibit presents a 12-month average of the standard deviations. Source: MSCI
capitalization and relative GDP may be driven by further valuation convergence. However, such valuation differentials are better exploited in fundamental–based tactical asset allocation strategies.

One simple exercise is to look back in time. What does the return of a GDP–weighted allocation to emerging and developed markets look like? Using an annual rebalancing based on the previous year's GDP weights, the average geometric return of a GDP–weighted allocation to emerging and developed markets produces an 8.3% annual average return. Using market capitalization weights, the return is 7.4%. The average annual outperformance of GDP weights is thus 102 basis points. While the volatility is slightly higher for the GDP weighted allocation, the Sharpe ratio is still higher using GDP instead of market capitalization weights.
6. Emerging asset classes in emerging markets

We have thus far focused the discussion on equities, but new asset classes are “emerging.” The emerging market corporate bond market has exploded in size. Ten years ago, US dollar-denominated emerging market corporate bonds represented a small fraction of sovereign issuance. Now, 86% of new issuance of emerging market dollar bonds is from corporations. Indeed, the emerging market corporate bond market now rivals the US high yield market in capitalization. Moreover, emerging markets seem to have overcome the “original sin” of being unable to borrow in their own currencies, and local currency debt markets are growing fast; see Burger, Warnock and Warnock (2012).

In addition, currencies have become more likely floating and investable. Investors can obtain emerging market currency exposure through investing in local currency emerging market bonds, or through forward contracts and options. Gilmore and Hayashi (2011) claim that the risk-return profile of long investments in emerging market currencies has been historically quite attractive. Importantly, the return of emerging market currencies mostly comes from their high “carry,” as they typically have higher yields than developed market currencies. Such a strategy features negative skewness, just as a carry strategy in developed market currencies does. Recently, however, interest rate differentials have converged across the world, making it somewhat unlikely that the historical performance of emerging market currencies will be repeated over the next decade.

---

3 See, for example, King and Williams (2013).
4 The carry trade involves investing in currencies with the highest interest rates and selling those currencies with low interest rates.
An important consideration here is how correlated equity markets are with their currencies. In developed markets such correlation is quite low and even often negative. For example, using monthly MSCI data between 1980 and 2012, we computed the correlation between currency changes relative to the dollar and the local equity markets (in local currency) for France, Germany, Italy, Japan, Canada and the UK. These correlations vary between −0.06 for the UK, and 0.43 for Canada, the latter partly explained by the Canadian currency being a commodity currency. If we repeat the same computations from the German rather than the US perspective, the correlations vary between −0.09 for the US and 0.20 for Italy. In emerging markets, however, these correlations are quite a bit higher. Exhibit 22 shows the correlation between the equity market return in local currency and the change in the dollar value of the local currency for 22 emerging markets. The correlations are invariably positive. Hence, for a US

Exhibit 23. Five-year trailing correlation of FX (US$ per local currency) changes and local currency MSCI equity returns for individual emerging markets

Investor, the currency increases the risk of the equity investment, and emerging market currencies and equities are not independent investments. One reason for this is that some emerging markets are rich in resources, and commodity currencies generally show higher correlations between their equity markets and currencies – as is, for instance, also true for Australia and Canada. Another reason is of course the fact that both the equity market and the currency market provide an option on the long-term economic performance of the country.

Exhibit 23, displaying five-year trailing correlations, shows that the correlation between equity markets and currencies has increased substantially for a number of countries, reducing their diversification potential.
7. Conclusions

Emerging markets represent less than 15% of world equity market capitalization, but more than 30% of world GDP. This does not necessarily make emerging markets attractive investments. Since the liberalization process in the late 80s and early 90s, the correlation between emerging markets and developed markets has increased substantially and valuation ratios have partially converged. However, recent research by Bekaert et al. (2011) suggests that emerging markets are still not fully integrated into world capital markets, and therefore that emerging markets should still be viewed as a separate asset class. Part of the increase in correlation is due to the higher beta of the emerging market index, making emerging markets high return but risky investments. At least historically, the “downside” beta seems to be lower than the “upside” beta, so that the increase in correlations has not eliminated diversification benefits as much as one might initially believe. Finally, the development of a large corporate and sovereign bond market as well as investable currencies has substantially increased the available investment opportunities in emerging markets for developed market investors.

Given these reflections, strategic allocations somewhere in between market capitalization weights and GDP weights are easy to defend. Institutional investors, however, appear still underweight in emerging markets. In 2011, MSCI conducted a survey of asset allocation and risk management practices across the world for institutional investors. Among the 85 participants, there were 35 public plans, 16 corporate plans, ten endowments/foundations or sovereign wealth funds, and 24 unclassified institutions. Exhibit 24 shows that the average allocation to emerging markets was
well below 15%; that is, less than the market capitalization weight of emerging markets. There is considerable dispersion across institutions with some allocating over 30% to emerging markets. The survey also found that there is a general trend towards decreased allocations to domestic and developed ex-domestic equities and towards increased exposures to emerging markets equities. Given the findings in our research, we expect this trend toward increased allocation to emerging markets to continue.

Our paper has important policy implications for investment management, and is particularly relevant for large institutional investors, such as pension funds and insurance companies. First, given that emerging markets are still not fully integrated into world capital markets, they should be treated as a separate asset class. Second, the share of world output accounted for by emerging markets is far greater than their share of equity market
capitalization. As a result, market capitalization weighting of emerging markets should be the minimal allocation, and the weight should ideally be higher than market capitalization. Third, any allocation to emerging markets should now include relatively new assets such as emerging market corporate bonds. Fourth, an institutional investor’s allocation must take into account the fact that emerging markets have evolved from an asset class with relatively low correlation with developed markets to an asset class with a much higher correlation. Finally, emerging market assets still have higher risk than most developed markets – and as a result, continue to command higher expected returns.

Emerging equity markets in a globalizing world

Given the dramatic globalization over the past twenty years, does it make sense to segregate global equities into “developed” and “emerging” market buckets? Geert Bekaert (Columbia University) and Campbell R. Harvey (Duke University) argue in this paper that the answer is still yes. While correlations between developed and emerging markets have increased, the process of integration of these markets into world markets is incomplete. Interestingly, this incomplete integration along with the relatively small equity market capitalization creates potentially attractive investment opportunities. This has important policy implications for institutional and pension fund management.
